# Practical Machine Learning Project

Ricardo Bull Feb 28, 2016

## **Prediction Assignment**

### Background

Using devices such as JawboneUp, NikeFuelBand, and Fitbitit is now possible to collect a large amount of data about personal activity relatively inexpensively. These type of devices are part of the quantified self movement - a group of enthusiasts who take measurements about themselves regularly to improve their health, to find patterns in their behavior, or because they are tech geeks. One thing that people regularly do is quantify how much of a particular activity they do, but they rarely quantify how well they do it.

In this project, the goal is to use data from accelerometers on the belt, forearm, arm, and dumbell of 6 participants. They were asked to perform barbell lifts correctly and incorrectly in 5 different ways. More information is available from the website: (http://groupware.les.inf.puc-rio.br/har)http://groupware.les.inf.puc-rio.br/har (http://groupware.les.inf.puc-rio.br/har) (see the section on the Weight Lifting Exercise Dataset).

### Preparing the data and R packages

Load packages, set caching

```
require(caret)
require(corrplot)
require(Rtsne)
require(xgboost)
require(stats)
require(knitr)
require(ggplot2)
knitr::opts_chunk$set(cache=TRUE)
```

### Getting Data

```
# URL of the training and testing data
train.url ="https://d396qusza40orc.cloudfront.net/predmachlearn/pml-training.csv"
test.url = "https://d396qusza40orc.cloudfront.net/predmachlearn/pml-testing.csv"
# file names
train.name = "./data/pml-training.csv"
test.name = "./data/pml-testing.csv"
# if directory does not exist, create new
if (!file.exists("./data")) {
 dir.create("./data")
# if files does not exist, download the files
if (!file.exists(train.name)) {
 download.file(train.url, destfile=train.name, method="curl")
}
if (!file.exists(test.name)) {
  download.file(test.url, destfile=test.name, method="curl")
}
# load the CSV files as data.frame
train = read.csv("./data/pml-training.csv")
test = read.csv("./data/pml-testing.csv")
dim(train)
```

```
## [1] 19622 160
```

dim(test)

## [155] "accel_forearm_y"
                                     "accel_forearm_z"
## [157] "magnet_forearm_x"
                                     "magnet_forearm_y"
## [159] "magnet_forearm_z"
                                     "classe"
```

The raw training data has 19622 rows of observations and 158 features (predictors). Column  $\,x\,$  is unusable row number. While the testing data has 20 rows and the same 158 features. There is one column of target outcome named classe.

### Data cleaning

First, extract target outcome (the activity quality) from training data, so now the training data contains only the predictors (the activity monitors).

```
# target outcome (label)
outcome.org = train[, "classe"]
outcome = outcome.org
levels(outcome)
```

```
## [1] "A" "B" "C" "D" "E"
```

Outcome has 5 levels in character format.

Convert the outcome to numeric, because XGBoost gradient booster only recognizes numeric data.

```
# convert character levels to numeric
num.class = length(levels(outcome))
levels(outcome) = 1:num.class
head(outcome)
```

```
## [1] 1 1 1 1 1 1
## Levels: 1 2 3 4 5
```

The outcome is removed from training data.

```
# remove outcome from train
train$classe = NULL
```

The assignment rubric asks to use data from accelerometers on the belt, forearm, arm, and dumbell, so the features are extracted based on these keywords.

```
# filter columns on: belt, forearm, arm, dumbell
filter = grepl("belt|arm|dumbell", names(train))
train = train[, filter]
test = test[, filter]
```

Instead of less-accurate imputation of missing data, remove all columns with NA values.

```
# remove columns with NA, use test data as referal for NA
cols.without.na = colSums(is.na(test)) == 0
train = train[, cols.without.na]
test = test[, cols.without.na]
```

## Preprocessing

### Check for features's variance

Based on the principal component analysis PCA, it is important that features have maximum variance for maximum uniqueness, so that each feature is as distant as possible (as orthogonal as possible) from the other features.

```
# check for zero variance
zero.var = nearZeroVar(train, saveMetrics=TRUE)
zero.var
```

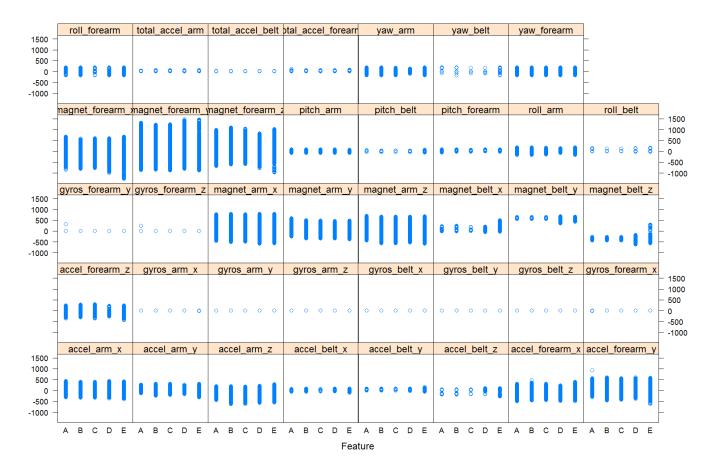

```
##
                        freqRatio percentUnique zeroVar

                                      8.5771073
                                                   FALSE FALSE
```

There is no features without variability (all has enough variance). So there is no feature to be removed further.

### Plot of relationship between features and outcome

Plot the relationship between features and outcome. From the plot below, each features has relatively the same distribution among the 5 outcome levels (A, B, C, D, E).

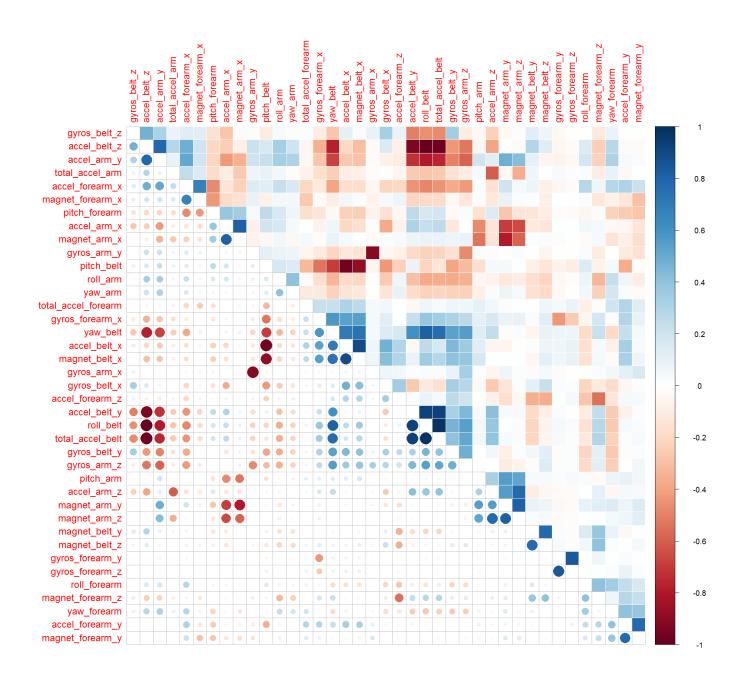

```
featurePlot(train, outcome.org, "strip")
```

### Plot of correlation matrix

Plot a correlation matrix between features.

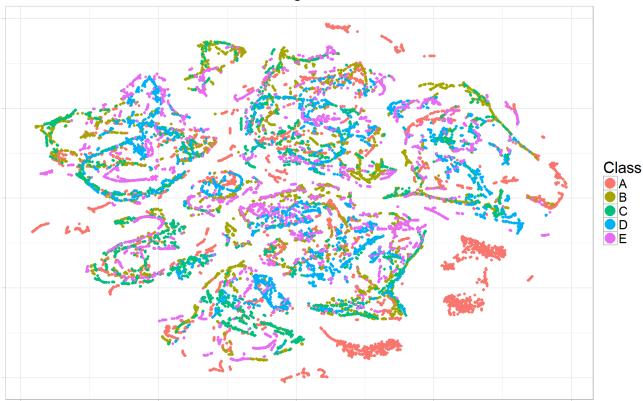

A good set of features is when they are highly uncorrelated (orthogonal) each others. The plot below shows average of correlation is not too high, so I choose to not perform further PCA preprocessing.

### tSNE plot

A tSNE (t-Distributed Stochastic Neighbor Embedding) visualization is 2D plot of multidimensional features, that is multidimensional reduction into 2D plane. In the tSNE plot below there is no clear separation of clustering of the 5 levels of outcome (A, B, C, D, E). So it hardly gets conclusion for manually building any regression equation from the irregularity.

### t-SNE 2D Embedding of 'Classe' Outcome

## Build machine learning model

Now build a machine learning model to predict activity quality (classe outcome) from the activity monitors (the features or predictors) by using XGBoost extreme gradient boosting algorithm.

### XGBoost data

XGBoost supports only numeric matrix data. Converting all training, testing and outcome data to matrix.

```
# convert data to matrix
train.matrix = as.matrix(train)
mode(train.matrix) = "numeric"
test.matrix = as.matrix(test)
mode(test.matrix) = "numeric"
# convert outcome from factor to numeric matrix
# xgboost takes multi-labels in [0, numOfClass)
y = as.matrix(as.integer(outcome)-1)
```

### XGBoost parameters

Set XGBoost parameters for cross validation and training.

Set a multiclass classification objective as the gradient boosting's learning function.

Set evaluation metric to merror, multiclass error rate.

```
# xgboost parameters
param <- list("objective" = "multi:softprob", # multiclass classification</pre>
             "num_class" = num.class, # number of classes
             "eval metric" = "merror",
                                        # evaluation metric
             "nthread" = 8, # number of threads to be used
             max_depth = 16,
                                # maximum depth of tree
             "eta" = 0.3, # step size shrinkage
                          # minimum loss reduction
             gamma = 0
             "subsample" = 1,
                               # part of data instances to grow tree
             "colsample_bytree" = 1, # subsample ratio of columns when constructing e
ach tree
             "min_child_weight" = 12 # minimum sum of instance weight needed in a chi
Ld
             )
```

### Expected error rate

Expected error rate is less than 1% for a good classification. Do cross validation to estimate the error rate using 4-fold cross validation, with 200 epochs to reach the expected error rate of less than 1%.

### 4-fold cross validation

```
## user system elapsed
## 422.09 16.47 134.31
```

Elapsed time is around 150 seconds (2.5 minutes).

```
tail(bst.cv$dt)
```

```
##
      train.merror.mean train.merror.std test.merror.mean test.merror.std
## 1:

                                                                     0.001071
## 3:
                       0
                                         0
                                                    0.005555
                                                                     0.001071
## 4:
                       0
                                                    0.005555
                                                                     0.001071
                                         0
## 5:
                       0
                                                    0.005606
                                                                     0.001135
                                         0
## 6:
                                                    0.005555
                                                                     0.001109
```

From the cross validation, choose index with minimum multiclass error rate.

Index will be used in the model training to fulfill expected minimum error rate of < 1%.

```
# index of minimum merror
min.merror.idx = which.min(bst.cv$dt[, test.merror.mean])
min.merror.idx
```

```
## [1] 187
```

```
# minimum merror
bst.cv$dt[min.merror.idx,]
```

```
## train.merror.mean train.merror.std test.merror.mean test.merror.std ## 1: 0 0 0.005402 0.000978
```

Best cross-validation's minimum error rate test.merror.mean is around 0.006 (0.6%), happened at 106th iteration.

### Confusion matrix

Tabulates the cross-validation's predictions of the model against the truths.

```
# get CV's prediction decoding
pred.cv = matrix(bst.cv$pred, nrow=length(bst.cv$pred)/num.class, ncol=num.class)
pred.cv = max.col(pred.cv, "last")
# confusion matrix
confusionMatrix(factor(y+1), factor(pred.cv))
```

```

                                                                0.9994
## Pos Pred Value
                          0.9975
                                    0.9934
                                             0.9889
                                                      0.9932
                                                                0.9972
## Neg Pred Value
                          0.9991
                                    0.9978
                                             0.9979
                                                      0.9985
                                                                0.9998
## Prevalence
                          0.2843
                                    0.1940
                                             0.1742
                                                      0.1640
                                                                0.1835
## Detection Rate
                          0.2837
                                    0.1922
                                             0.1725
                                                      0.1628
                                                                0.1833
## Detection Prevalence
                          0.2844
                                    0.1935
                                             0.1744
                                                      0.1639
                                                                0.1838
## Balanced Accuracy
                          0.9984
                                    0.9946
                                             0.9939
                                                      0.9956
                                                                0.9991
```

Confusion matrix shows concentration of correct predictions is on the diagonal, as expected.

The average accuracy is 99.38%, with error rate is 0.62%. So, expected error rate of less than 1% is fulfilled.

### Model training

Fit the XGBoost gradient boosting model on all of the training data.

```
## user system elapsed
## 131.06 3.95 46.62
```

Time elapsed is around 35 seconds.

### Predicting the testing data

```
# xgboost predict test data using the trained model
pred <- predict(bst, test.matrix)
head(pred, 10)</pre>
```

```
## [1] 2.722199e-04 9.982042e-01 1.132105e-03 1.515472e-04 2.398420e-04
## [6] 9.991074e-01 6.353945e-04 2.402208e-04 3.893657e-06 1.299460e-05
```

### Post-processing

Output of prediction is the predicted probability of the 5 levels (columns) of outcome. Decode the quantitative 5 levels of outcomes to qualitative letters (A, B, C, D, E).

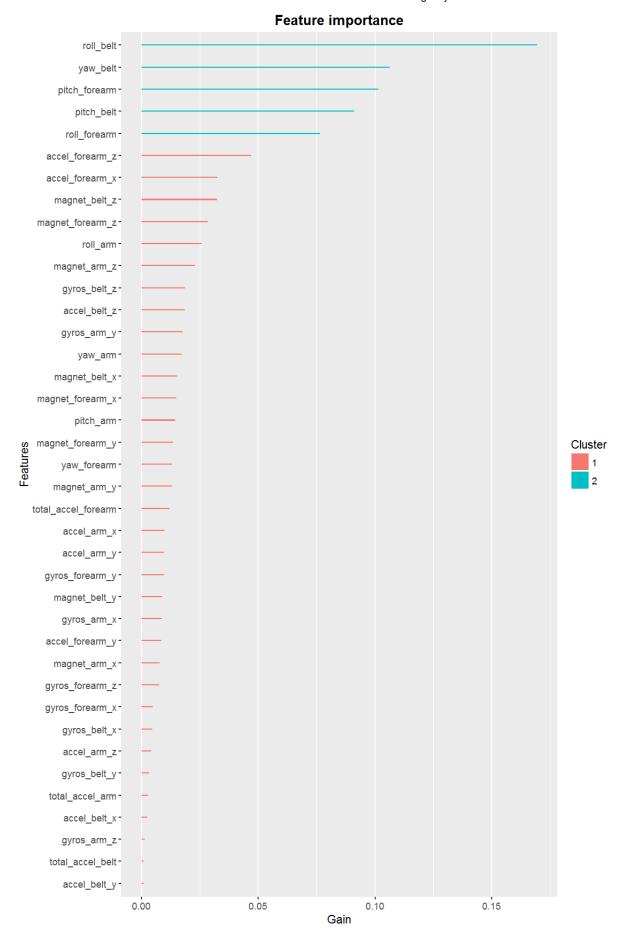

```
# decode prediction
pred = matrix(pred, nrow=num.class, ncol=length(pred)/num.class)
pred = t(pred)
pred = max.col(pred, "last")
pred.char = toupper(letters[pred])
```

(The prediction result pred.char is not displayed intentionally due to Honour Code, because it is the answer of the "project submission" part.)

### Feature importance

```
# get the trained model
model = xgb.dump(bst, with.stats=TRUE)
# get the feature real names
names = dimnames(train.matrix)[[2]]
# compute feature importance matrix
importance_matrix = xgb.importance(names, model=bst)

# plot
gp = xgb.plot.importance(importance_matrix)
print(gp)
```

Feature importance plot is useful to select only best features with highest correlation to the outcome(s). To improve model fitting performance (time or overfitting), less important features can be removed.

## Creating submission files
